# **ProductInformation**

MDR1, human recombinant, expressed in *Sf*9 cells, membrane preparation, for ATPase

Product Number **M9194** Storage Temperature –70 °C

## **TECHNICAL BULLETIN**

## **Product Description**

Multi-drug resistance (MDR) is a major factor in the failure of many forms of chemotherapy; one that affects patients with a variety of hematological malignancies and solid tumors, including different types of leukemia, breast, ovarian, lung, and lower gastrointestinal tract cancers. In the past few years it has become accepted that the resistance to chemotherapy correlates with the overexpression of at least two ATP-dependent drugefflux pumps. These cell membrane proteins, called P-glycoprotein (MDR1, PgP, ABCB1) and multidrugresistance-associated protein (MRP1), are members of the ATP-binding-cassette (ABC) transporter family.

The MDR1 protein is involved in cancer drug resistance and in the transport of hydrophobic drugs and xenobiotics in the bowel, kidney, liver, and the bloodbrain barrier. Drugs interacting with this protein may be useful for the reversal of cancer drug resistance or for increasing the absorption or the brain entry of various pharmacological agents.

The ABC transporters pump substrates out of the cell by using hydrolysis of ATP as an energy source. Detection of the ATPase activity of the MDR1 protein is a measure of transporter activity. The assay is performed using purified membrane vesicles from *Sf9* (*Spodoptera frugiperda*) cells, expressing high levels of MDR1 protein.

This kit uses an ATPase assay procedure for measuring human MDR1 activity. ATP hydrolysis yields inorganic phosphate (P<sub>i</sub>), which can be detected by a simple colorimetric reaction. The amount of P<sub>i</sub> liberated is proportional to the activity of the transporter. <sup>6</sup>

Membrane preparations containing ABC transporters show a baseline ATPase activity that varies for different transporters. Transported substrates increase this baseline ATPase activity, while inhibitors or slowly transported compounds inhibit the baseline ATPase activity and/or the ATPase activity measured in the presence of a stimulating agent. Both activation and inhibition studies can be performed.

## Reagent

The membrane vesicles are suspended in TMEP solution (50 mM Tris-HCl, 50 mM mannitol, 2 mM EGTA, 8  $\mu$ g/ml aprotinin, 10  $\mu$ g/ml leupeptin, 50  $\mu$ g/ml PMSF, and 2 mM DTT, pH 7.0)

## Equipment and Reagents Required But Not Provided

- Trizma<sup>®</sup> base [Tris(hydroxymethyl)aminomethane, Tris-base], Product Code T1503
- MOPS [3-(N-Morpholino)propanesulfonic acid], Product Code M1254
- Ethylene glycol-bis(2-aminoethylether)-*N*,*N*,*N*',*N*'-tetraacetic acid (EGTA), Product Code E3889
- Potassium chloride (KCI), Product Code P9333
- Sodium azide (NaN<sub>3</sub>), Product Code S8032
- DL-Dithiothreitol (DTT), Product Code D5545
- Sodium dodecyl sulfate (SDS), Product Code L6026
- Potassium phosphate monobasic (KH<sub>2</sub>PO<sub>4</sub>), Product Code P5379
- (±)-Verapamil hydrochloride, Product Code V4629
- Sodium orthovanadate (Na<sub>3</sub>VO<sub>4</sub>), Product Code S6508
- Adenosine 5'-triphosphate, disodium salt (ATP), Product Code A2383
- Magnesium chloride hexahydrate, Product Code M2670

- Zinc acetate dihydrate, Product Code 383058
- Ammonium molybdate tetrahydrate, Product Code A7302
- Ascorbic acid
- Dimethyl sulfoxide (DMSO), Product Code D2650
- Ultrapure water (17 M $\Omega$ ·cm or equivalent)
- 37 °C water bath/incubator
- Multichannel pipettes with corresponding tips
- 96 well plates and plate reader with absorbance filter suitable for measuring absorbance between 630–850 nm

#### Precautions and Disclaimer

This product is for R&D use only, not for drug, household, or other uses. Please consult the Material Safety Data Sheet for information regarding hazards and safe handling practices.

### **Preparation Instructions**

Use ultrapure water (17 M $\Omega$ ·cm or equivalent) for preparation of reagents.

- 1.7 M Tris Solution Dissolve 20.587 g of Tris-base in 100 ml of water. The solution may be stored at 2–8  $^{\circ}$ C for at least 1 year.
- 0.1 M MOPS-Tris Solution Dissolve 2.09 g of MOPS in 90 ml of water and adjust pH to 7.0 with 1.7 M Tris Solution (–2 ml). Bring the final volume to 100 ml with water. The solution may be stored at 2–8 °C for at least 1 year.
- 100 mM EGTA-Tris, pH 7.0 Solution Dissolve 3.804 g of EGTA in  $\sim$ 10 ml of 1.7 M Tris Solution. Add 80 ml of water and adjust pH to 7.0 with 1.7 M Tris Solution. Bring the final volume to 100 ml with water. The solution may be stored at 2–8 °C for at least 1 year.
- 1 M KCl Solution Dissolve 7.46 g of KCl in 100 ml of water. The solution may be stored at 2–8 °C for at least 1 year.
- 0.1 M Sodium Azide Solution Dissolve 0.65 g of sodium azide in 100 ml of water. The solution may be stored at 2-8 °C for at least 1 year.
- 0.1 M DTT Solution Dissolve 0.3086 g of DTT in 20 ml of water. Store the solution in aliquots at –20 °C.
- 5% SDS Solution Dissolve 5 g of SDS in 100 ml of water. The solution may be stored at room temperature for at least 1 year.

60 mM Sodium Orthovanadate Solution – prepared in water. Store the solution in aliquots at -20 °C.

100 mM KH $_2$ PO $_4$  Solution – Dissolve 0.1361 g of KH $_2$ PO $_4$  in 10 ml of water. Store the solution in aliquots at –20  $^{\circ}$ C.

Phosphate Standard Solutions - 0.5 mM, 1 mM, 2 mM, 4 mM, and 8 mM  $KH_2PO_4$  solutions prepared with water from 100 mM  $KH_2PO_4$  Solution. Store the solutions in aliquots at -20 °C.

0.2 M Mg-ATP Solution – Dissolve 2.2 g of ATP and 0.813 g of MgCl $_2$  in 10 ml of water and adjust pH to 7.0 with 1.7 M Tris Solution. Bring final volume to 20 ml with water. Store the solution in aliquots at –20 °C.

2 mM Verapamil Solution – Prepare in DMSO. Store the solution in aliquots at –20 °C.

15 mM Zinc Acetate Solution – Dissolve 330 mg of Zinc Acetate in 100 ml of water. The solution may be stored at 2–8 °C for at least 2 weeks.

35 mM Ammonium Molybdate and 15 mM Zinc Acetate, pH 5.0 Solution – Dissolve 0.432 g of Ammonium Molybdate in 10 ml of 15 mM Zinc Acetate Solution. Store in a container wrapped with aluminum foil in the dark. Freshly prepare the solution.

10% Ascorbic Acid, pH 5.0 Solution – Dissolve 3 g of Ascorbic Acid in 30 ml of water and adjust pH to 5.0 with NaOH. Freshly prepare the solution.

Assay Mix - Combine the following:

0.1 M MOPS-Tris Solution	5,000 μl
1 M KCl Solution	500 μl
0.1 M Sodium Azide Solution	500 μl
0.1 M DTT Solution	200 µl
100 mM EGTA-Tris, pH 7.0 Solution	10 μΙ
water	3,790 µl

Total volume  $10,000 \mu l$ 

Add the 0.1 M DTT Solution just prior to use. The rest of the solutions can be pre-mixed and stored at 2-8 °C.

## Storage/Stability

The product ships on dry ice and storage at -70 °C is recommended. The membrane activity is not significantly lost after one freeze-thaw cycle. For long term storage, freeze in working aliquots.

#### Procedure

#### A – Assays for Activation Studies

Some test compounds may have absorbance between 630–850 nm or interfere with the assay in other ways. In order to separate any nonspecific effects, test compounds should be assayed with and without the presence of 1.2 mM Na<sub>3</sub>VO<sub>4</sub>. See Table 1 for suggested layout of activation assays.

See method B for information on control assays.

- Assemble the Assay Mix and keep it on ice. Place a 96 well plate on ice.
- 2. Add 40  $\mu$ l of Assay Mix to the wells used for P<sub>i</sub> calibration curve. Add 10  $\mu$ l of the Phosphate Standard Solutions to the appropriate wells (to obtain a range of 5–80 nmoles of P<sub>i</sub> per well). Add 40  $\mu$ l of 5% SDS Solution to these wells. Perform in duplicates.
- For MDR1 assays, use the predetermined membrane protein concentration (5 mg/ml) to prepare a 1 mg/ml suspension by diluting the membranes with Assay Mix (mix well).
- 4. Add 40 μl of the prepared membrane suspension to the appropriate wells of the 96 well plate.

- 5. Add test compounds in 1 μl of DMSO. Throughout this procedure DMSO is used as a general solvent of test compounds; the final concentration of DMSO is 2% in the assay during the incubation period. Controls are also designed according to this. However, the assay tolerates up to 2% of a wide range of organic solvents (DMSO, ethanol, methanol, and acetonitrile). If you are using a different solvent replace DMSO with that solvent in all controls.
- Transfer plates to 37 °C and preincubate for 5 minutes.
- 7. Prepare a 25 mM Mg-ATP Solution by diluting 0.2 M Mg-ATP Solution with Assay Mix.
- 8. Start the ATPase reaction by the addition of 10  $\mu$ l of 25 mM Mg-ATP Solution.
- 9. For the MDR1 assay, incubate the plates at 37 °C for 20 minutes.
- 10. Stop the ATPase reaction by adding 40  $\,\mu$ l of 5% SDS Solution to each well.
- 11. Prepare the Detection Reagent: Add 5 ml of 35 mM Ammonium Molybdate and 15 mM Zinc Acetate, pH 5.0 Solution to 15 ml of the freshly prepared 10% Ascorbic Acid, pH 5.0 Solution. Invert to mix.
- 12. Add 200 μl of Detection Reagent to each well.
- 13. Incubate the plates at 37 °C for 25 minutes and read the absorbance between 630–850 nm. Note: A slow increase in absorbance will continue in the ATP-containing wells, due to ATP cleavage caused by the Detection Reagent.

**Table 1.**Activation Assay Layout Guidelines – It is designed for a duplicate measurement of 2 different compounds at 8 concentrations (3-fold serial dilution starting from 100 μM).

#### B – Control Assays

As a result of the multiple reactions occurring during the assay, transporter activities from absorbance values can only be calculated with adequate controls. Therefore, it is important to understand how the different experimental conditions modify the measured absorbance values, reflecting  $P_i$  concentration. The  $P_i$  measured is composed of the following elements:

There is some  $P_i$  present in the final assay suspension containing the membranes and ATP. This is mainly due to the contamination of the membranes and ATP with  $P_i$ , and some non-enzymatic ATP hydrolysis.

Some of the ATPase activity in the membranes is  $Na_3VO_4$  insensitive. It is important to determine this activity, since the transporter-specific  $Na_3VO_4$  sensitive activity can only be calculated by subtracting this background  $Na_3VO_4$  insensitive activity. This activity may vary with membrane stocks, thus including this control in the calculations also decreases inter-assay variability.

Membranes always contain a small amount of  $Na_3VO_4$  sensitive ATPase activity not related to transporter ATPase. This activity is low and does not significantly impact the results of the assay. To confirm this, an optional fifth control may be run. The  $Na_3VO_4$  sensitive ATPase activity may be measured using control membranes expressing a mutant (defective) variant of the MRP1 transporter (Product Code M9819; MDR1, MRP, and BSEP Control). The  $Na_3VO_4$  sensitive ATPase activity may also be measured using control membranes expressing β-galactosidase. This assay is routinely performed to validate membrane production and purification. Control membranes expressing β-galactosidase are available from SOLVO Biotechnology.

The rest of the signal is the transporter specific ATPase activity of the membrane suspension, which is Na<sub>3</sub>VO<sub>4</sub> sensitive. Transporters show some baseline ATPase activity that varies for different transporters and different membrane preparations. Substrates of the transporter stimulate the baseline ATPase activity, while inhibitors or slowly transported compounds inhibit the baseline ATPase activity.

It is suggested the following controls be set up for measuring the different elements of the signal. Perform all controls in duplicates.

If you are using a solvent other than DMSO, replace DMSO with that solvent in all controls.

Control 1 – Assay Background Control: Add 40  $\mu$ l of 1 mg/ml prepared membrane suspension (step A,3) and 40  $\mu$ l of 5% SDS Solution to the wells. Add 1  $\mu$ l of DMSO. Preincubate at 37 °C for 5 minutes. Add 10  $\mu$ l of 25 mM Mg-ATP Solution (step A,7) to the wells and incubate at 37 °C. Develop color reaction for inorganic phosphate. This will show the P<sub>i</sub> present in the well without any enzymatic ATP hydrolysis. Control 1 serves as a quality check of the components of the assay mix, solvents, ATP, and membrane used.

Control 2 – Na $_3$ VO $_4$  Insensitive ATPase Activity: Add 40  $\mu$ l of 1 mg/ml prepared membrane suspension (step A,3) and 1  $\mu$ l of 60 mM Sodium Orthovanadate Solution to the wells (final Na $_3$ VO $_4$  concentration is 1.2 mM). Add 1  $\mu$ l of DMSO. Preincubate at 37 °C for 5 minutes. Start the reaction by adding 10  $\mu$ l of 25 mM Mg-ATP Solution (step A,7) to the wells and incubate at 37 °C. Stop the reaction by adding 40  $\mu$ l of 5% SDS Solution per well at the end of the incubation period and develop color reaction for inorganic phosphate. This will show the ATPase activity insensitive to Na $_3$ VO $_4$ .

Control 3 – Baseline ATPase Activity: Add 40  $\mu$ l of 1 mg/ml prepared membrane suspension (step A,3) and 1  $\mu$ l of DMSO to the wells. Preincubate at 37 °C for 5 minutes. Start the reaction by adding 10  $\mu$ l of 25 mM Mg-ATP Solution (step A,7) to the wells and incubate at 37 °C. Stop the reaction by adding 40  $\mu$ l of 5% SDS Solution to each well at the end of the incubation period and develop color reaction for inorganic phosphate. This will show the basic level of P<sub>i</sub> liberation in the presence of a given membrane, transporter, and solvent for the test compounds. For obtaining the vanadate-sensitive baseline ATPase activity subtract Control 2.

Control 4 – Fully Activated (Maximal) ATPase Activity: Add 40  $\mu$ l of 1 mg/ml prepared membrane suspension (step A,3). For MDR1 ATPase activity, add 1  $\mu$ l of 2 mM Verapamil Solution (final concentration of verapamil is 40  $\mu$ M). Preincubate at 37 °C for 5 minutes. Start the reaction by adding 10  $\mu$ l of 25 mM Mg-ATP Solution (step A,7) to the wells and incubate at 37 °C. Stop the reaction by adding 40  $\mu$ l of 5% SDS Solution to each well at the end of the incubation period and develop color reaction for inorganic phosphate. This will show the maximum level of P<sub>i</sub> liberation in the presence of a given membrane and transporter. For obtaining the full vanadate-sensitive ATPase activity subtract Control 2.

#### C – Assavs for Inhibtion Studies

Note that in case of inhibition studies test compounds are assayed in the presence of a strong activator.

Some compounds may have absorbance between 630–850 nm or interfere with the assay in other ways. In order to separate any nonspecific effects, test compounds should be assayed with and without the presence of 1.2 mM Na<sub>3</sub>VO<sub>4</sub>. See Table 2 for suggested layout of inhibition assays.

See method B for information on control assays.

- 1. Perform steps A1 and A2.
- For MDR1 assays, use the predetermined membrane protein concentration (5 mg/ml) to prepare a 1 mg/ml suspension by diluting the membranes with Assay Mix (mix well). In inhibition studies, remove the amount of prepared membrane suspension required for controls (8 wells). Add the strong activator to the rest of the suspension: 25 μl of 2 mM Verapamil Solution per ml of membrane suspension (final concentration of verapamil is 40 μM).
- 3. Perform steps A4 A13

Table 2.

Inhibition Assay Layout Guidelines – It is designed for a duplicate measurement of 2 different compounds at 8 concentrations (3-fold serial dilution starting from 100 μM). Note that in case of inhibition studies test compounds are assayed in the presence of a strong activator.

#### Results

There are two presentations of the data:

### A. Calculation of Specific Activities:

Calculate the Na<sub>3</sub>VO<sub>4</sub> sensitive transporter ATPase activities in terms of P<sub>i</sub> liberated/mg membrane protein/min. This is obtained by subtracting the P<sub>i</sub> liberated in the presence of Na<sub>3</sub>VO<sub>4</sub> from the P<sub>i</sub> liberated without Na<sub>3</sub>VO<sub>4</sub>. P<sub>i</sub> liberated is determined using a KH<sub>2</sub>PO<sub>4</sub> calibration curve and the results are calculated based on the amount of membrane protein/well and incubation time.

Calculation of the specific Na<sub>3</sub>VO<sub>4</sub> sensitive transporter ATPase activities:

1. Calculate the average absorbance values of the duplicate measurements of the Phosphate Standard Solutions, controls (Control 1, 2, 3, 4), and test samples.

- 2. Set up a calibration curve using the absorbance values of the Phosphate Standard Solutions and the amount of KH<sub>2</sub>PO<sub>4</sub> used (nmol/well).
- Determine the nanomoles of P<sub>i</sub> liberated in the controls and in the samples by using the calibration curve and the average absorbance values calculated in steps 1 and 2.
- Subtract P<sub>i</sub> liberated in Control 2 from P<sub>i</sub> liberated in Control 3. This will give you the baseline Na<sub>3</sub>VO<sub>4</sub> sensitive ATPase activity.
- Subtract P<sub>i</sub> liberated in Control 2 from P<sub>i</sub> liberated in Control 4. This will give you the fully activated Na<sub>3</sub>VO<sub>4</sub> sensitive transporter ATPase activity.
- 6. Subtract the P<sub>i</sub> values determined in the presence of Na<sub>3</sub>VO<sub>4</sub> from the P<sub>i</sub> values measured without Na<sub>3</sub>VO<sub>4</sub> for each compound examined. This will give you the Na<sub>3</sub>VO<sub>4</sub> sensitive transporter ATPase activity for each test compound and test compound concentration assayed.

 Calculate the Na<sub>3</sub>VO<sub>4</sub> sensitive transporter ATPase activity in terms of P<sub>i</sub> liberated/mg membrane protein/min. Divide the numbers by the amount of membrane protein added to one well and the time of incubation in minutes.

#### Expected results:

Typical baseline and maximal Na<sub>3</sub>VO<sub>4</sub> sensitive ATPase activities of the MDR1 transporter (nmol P<sub>i</sub>/mg membrane protein/min):

MDR1 transporter

Baseline activity 8-16

Maximal activity 35-60

In activation studies, test compounds that are activators of the baseline transporter ATPase activity will increase the rate of ATP cleavage compared to the baseline ATPase activity. The  $Na_3VO_4$  sensitive transporter ATPase activity will fall between the baseline  $Na_3VO_4$  sensitive ATPase activity and the fully activated  $Na_3VO_4$  sensitive ATPase activity. Inhibitors of the baseline ATPase activity will decrease the rate of ATP cleavage compared to the baseline ATPase activity. The  $Na_3VO_4$  sensitive transporter ATPase activity will be between 0 and the baseline  $Na_3VO_4$  sensitive ATPase activity.

In inhibition studies, test compounds that are inhibitors of the maximal and/or the baseline ATPase activity will decrease the rate of ATP cleavage compared to the fully activated ATPase activity. The Na<sub>3</sub>VO<sub>4</sub> sensitive transporter ATPase activity will be between 0 and the maximal Na<sub>3</sub>VO<sub>4</sub> sensitive ATPase activity.

# B. <u>Calculation of Percent Transporter ATPase</u> Activities:

In this presentation the baseline ATPase activity (Control 3) and the maximal ATPase activity (Control 4) are taken as 0% and 100% transporter ATPase activity, respectively. Absorbance values determined in the presence of test compounds are represented as percent activity on this relative scale. Note that some compounds are inhibitors of the baseline transporter ATPase activity. These will show negative percent values in this representation.

Calculation of the percent transporter ATPase activities:

- Subtract Control 3 from Control 4. This will give you the absorbance representing the maximal Na<sub>3</sub>VO<sub>4</sub> sensitive compound stimulated transporter ATPase activity.
- 2. Subtract Control 2 from Control 3. This will give you the absorbance representing the baseline Na<sub>3</sub>VO<sub>4</sub> sensitive transporter ATPase activity.
- 3. Subtract the absorbance values measured in the presence of Na<sub>3</sub>VO<sub>4</sub> from the absorbance values measured without Na<sub>3</sub>VO<sub>4</sub> for each test compound and subtract the absorbance representing the baseline Na<sub>3</sub>VO<sub>4</sub> sensitive ATPase activity (step 2) from every difference. This will give you the absorbance representing the compound stimulated transporter ATPase activity for each compound and compound concentration assayed.
- Calculate the percent transporter ATPase activities. Simply divide each absorbance value from step 3 by the absorbance value calculated in step 1. Multiply the result by 100 to get the results in percentage.

## Expected results:

The maximal compound stimulated transporter ATPase activities are determined in the presence of a strong activator of the transporter. In activation studies, compounds tested are not expected to give significantly higher activation even at the highest concentrations used, so results greater than 100% are not common. Some compounds are inhibitors (or in some cases, activators at lower concentrations and inhibitors at higher concentrations) of the baseline transporter activity. In this case the percent stimulation may turn into negative numbers. Further insight into the ATPase inhibitory effect of compounds can be gained by performing inhibition studies.

In inhibition studies, percent inhibition values usually fall between 0–100%. However, if a certain compound inhibits both the maximal Na<sub>3</sub>VO<sub>4</sub> sensitive ATPase activity and the baseline Na<sub>3</sub>VO<sub>4</sub> sensitive ATPase activity, percent inhibition values may turn into negative numbers. Detailed information on whether a certain compound inhibits the baseline ATPase activity and/or the maximal ATPase activity of the transporter can be gained by assaying the test compound for both activation and inhibition.
